

Idea_before

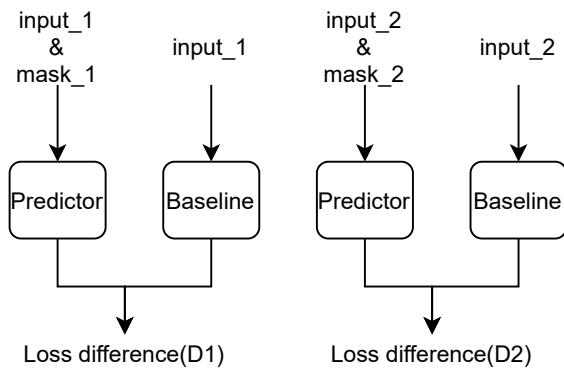

Step 1: feed input_1, input_2, input_3 into selector

Step 2.1: train predictor and baseline as binary classification

Step 2.2: get loss difference for input_1 and input_2 separately

Step3: an approximated loss of selector

$$\frac{1}{2}(D1 \bullet \text{prob_1} + D2 \bullet \text{prob_2}) + \text{marginloss}(\text{prob_1}, \text{prob_2}, \text{prob_3})$$

Idea_now

Step 2.2: get only one pairwise loss difference

Step3: an approximated loss of selector

$$\frac{1}{2}(\text{prob_1} + \text{prob_2}) \bullet D + \text{marginloss}(\text{prob_1}, \text{prob_2}, \text{prob_3})$$
